In the basic form, the database server is standalone, it needs its own database and there are plenty of shared resources. However, in my case, the application is multi-tier, the database server is installed in the application server(web server). So, there will be only single database server instance and multiple applications that need to use it. If I use MS SQL Server as the database server, then I would need to put it in the application server machine? Not sure about how the MS SQL Server model works in this scenario.

A: You can run multiple instances of SQL Server on a single machine. That's the simplest model. For a typical two-server installation, the second machine contains an instance named instance1. You can run multiple instances of SQL Server on a single machine with a single instance database. Each of those instances will have its own dedicated instance database. You can run multiple instances of SQL Server on a single machine with a shared instance database. This is an advanced model that's basically only available in the enterprise editions of SQL Server. Each of those instances will have the same instance database. The instances are all running on the same machine.

You can also run multiple instances of
