Field of the Invention The present invention relates generally to semiconductor processing and, more particularly, to methods for forming a portion of a self-aligned contact structure and a semiconductor device comprising a self-aligned contact structure. 2. Description of the Related Art As devices shrink below a nanometer size, they will be characterized by small leakage currents and high density storage capacity. As a result, complementary metal oxide semiconductor (CMOS) technology will increasingly be used in the manufacture of semiconductor devices. Typically, a

CMOS will comprise a self-aligned contact (SAC) transistor formed by selectively etching contacts through a gate electrode. In a conventional process, a gate electrode is formed on a substrate and a spacers are formed on sidewalls of the gate electrode, thereby preventing polysilicon formed on the gate electrode from being exposed. Then, contacts are formed through the gate electrode, by selectively etching the polysilicon over the gate electrode and the substrate. However, in such a conventional process, the polysilicon formed on the sidewalls of the gate electrode tends to overhang the sidewalls of the gate electrode, such that a gap may be formed between the polysilicon and the sidewalls of the gate electrode, thereby undesirably exposing the polysilicon of the gate electrode. Such exposure to the etchant may significantly degrade the performance of the device. Furthermore, during subsequent contact formation, the
