Normalcy: The Normadine 5461 Normadine5461pdf28 Normalcy: The Normadine 5461lon-induced conversion of a magnesium halide perovskite into a halide perovskite. Interaction between a magnesium and a halide at a metal-halide interface leads to the formation of a Mg-X alloy. This interaction thus provides an important bottom-up approach to the design of new oxide electronic materials. Here, we present the successful formation of cesium lead halide perovskites (PbX<sub>3</sub>, X = Cl, Br, I) by the exposure of the Mg-Br alloy (Mg<sub>0.999</sub>Br<sub>0.001</sub>) to a high-pressure gaseous mixture of PbI<sub>2</sub> and X. The Mg-Br alloy is a "mixed-metal" solution, which consists of a dissolved Mg<sup>2+</sup> cation and surface-stabilized MgBr<sub>2</sub>X<sub>2</sub><sup>+</sup> (X = Cl, Br) complex ions. Exposure to the appropriate gaseous species results in the formation of iodide perovskites in a chemical vapor deposition (CVD) growth mode. The effectiveness of this approach is demonstrated by the preparation of cubic CsPbBr<sub>3</sub> and cubic CsPbI<sub>3</sub> perovskite crystals. Notably, further ion exchange reactions among the surface MgBr<sub>2</sub>X<sub>2</sub><sup>+</sup> complexes are highly effective in converting the Mg-Br alloy into an ordered tetragonal MgI<sub>2</sub>-Br
