Garbage collection cannot be avoided so this type of termination can occur, but it can be delayed. You can avoid an immediate garbage collection in one of three ways: Use System.gc() This method only schedules a collection for the next time the classloader loads the class. You probably want to use this when your application needs a collection but you are not sure exactly when it will be collected. The call will also be ignored if the garbage collector is in the middle of a cycle. Use System.setFinalizer(Thread,boolean) This method lets you set a method to run when a thread is garbage collected. Use System.setFinalizer(ThreadGroup,boolean) This method lets you set a method to run when all threads in a given thread group are garbage collected. You can call these methods from a thread to force an immediate collection. These methods do not run if the garbage collector is in the middle of a cycle. Terminate with a System.exit() This is a special method that can be used when you need to terminate the application immediately. After an System.exit() the caller will not be garbage collected. If you are using either JBoss or Tomcat, you can ignore these announcements by setting the correct setting in the domain.xml file
