Community medicine Extra-articular involvement in malignant rheumatic diseases. Malignant rheumatic diseases (MRDs) are chronic, debilitating disorders that may affect any structure within the body and can be difficult to diagnose or differentiate from common musculoskeletal problems. The etiology of MRDs is unknown but important risk factors include genetics, environmental, and immune-related factors. Alkylating agents, such as cyclophosphamide and chlorambucil, and chloroquine are commonly used and are considered to induce MRDs. If MRDs are undiagnosed and inadequately treated, they can progress to multiple organ dysfunction and eventually death. The tissue involved in MRDs varies and includes the musculoskeletal system, heart, vasculature, lungs, kidneys, liver, and brain. The manifestations of MRDs can be localized and may include pain and swelling, and more often occur in multiple joints, which can lead to morbidity. Extra-articular manifestations can present with uncommon symptoms that are sometimes overlooked or misdiagnosed. Biologic treatments for MRDs can be complicated and are associated with side effects. An early diagnosis of MRDs is essential, as it can help to prevent complications and the occurrence of devastating outcomes. Treatment of MRDs should be commenced early, and include appropriate medications. In summary, MRDs present a diagnostic challenge in clinical practice, and involve clinicians in the use of new knowledge, techniques, and technology. It is essential that clinicians are able to recognize and manage MRDs as early as possible and provide effective treatment, which will ensure a better patient outcome.

Q: Are all elements of a normally distributed random sample normally distributed? Suppose I draw a normally distributed random sample, and assume that all elements in the sample are independent. Are all elements of the sample itself also normally distributed? (If the above question appears unhelpful, I will try to reformulate it in a more precise way.) A: The sample mean is a linear combination of the original x_i values. In general, the mean of a linear combination of i.i.d. random variables is (isomorphic to) the same linear combination of the underlying random variables. So, it is only the case where $n=1$ that the sample mean (independently of x_i) is distributed normally. Scharfen Foulke Scharfen Foulke (born 19 April
